Exam-style questions with solutions

Part 1: Electrical systems

Abbreviations:

KVL: Kirchhoff's voltage law

KCL: Kirchhoff's current law

LHS: left-hand side (of the equation)

Question 1: Consider the schematic of an electrical circuit depicted below, consisting of a resistor, an inductor, and a capacitor

(with parameters R, L, and C, respectively). The charge accumulated on the capacitor is denoted as q(t). An external voltage is applied to the circuit, denoted as v(t). Find the differential equation model of the system relating v(t) and q(t).

Solution: Penoting the voltage drops across the circuit elements as VR, VL, and Vc, respectively,

and invoking KVL, we write:

The question asks us to relate V and q, thus we need to rewrite Ve and Vi in terms of q $(Using \dot{z} = \dot{q}):$ $V_{R} = R \cdot \dot{z} = R \cdot \dot{g}$ $V_L = L \cdot \dot{z} = L \cdot \ddot{q}$ Rewriting KVL with these, we find: $\mathcal{O} = R\dot{q} + L\dot{q} + \frac{1}{c}q$

Question 2: Consider the schematic of an electrical circuit depicted below, consisting of a resistor, an inductor, and a capacitor

(with parameters R, L, and C, respectively). The voltage drop across the resistor is denoted as v2(t). An external voltage is applied

to the circuit, denoted as v1(t). Find the differential equation model of the system relating v1(t) and v2(t).

Involving KCL at point A:

il = ic + ir Involving KVL for left loop:

 $v1 = V_L + v2$

The question asks us to relate

v1 and v2, thus we need to

rewrite VL and Vc in terms of v2

Writing the linear model of the

inductor: $V_L = L \cdot \dot{z}_L$

Rewriting KVL with this:

$v1 = L \dot{i}_L + v2$

Rewriting $i_L = i_C + i_R$

with these, we have:

Substituting this in the KVL

Question 3: Consider the schematic of an electrical circuit depicted below, consisting of a resistor, an inductor, and a capacitor (with parameters R, L, and C, respectively). The current flowing through the inductor is denoted as iL(t). An external current is supplied to the circuit, denoted as i(t). Find the differential equation model of the system relating i(t) and iL(t).

From linear models of the inductor and

the resistor, we can write:

 $V_{L} = L \cdot \dot{z}_{L} \qquad V_{R} = R \cdot \dot{z}_{L}$

Rewriting KVL with these:

 $V_{C} = L \cdot \dot{z_{L}} + R \cdot \dot{z_{L}}$

Differentiating both sides:

 $V_{c} = L \cdot i_{L} + R \cdot i_{L}$

Multiplying both sides by C:

 $\int C \cdot \dot{V}_{c} = L \cdot C \cdot \dot{i}_{L} + R \cdot C \cdot \dot{z}_{L}$

From linear model of the

 $capacitor: \dot{z}_{c} = C \cdot V_{c}$

IThis equation thus becomes:

 $\int \dot{i}_{C} = L \cdot C \cdot \dot{i}_{L} + R \cdot C \cdot \dot{i}_{L}$

From KCL at point A we found:

 $\dot{z} = \dot{z}_{c} + \dot{z}_{L}$, thus: $\dot{z}_{c} = \dot{z} - \dot{z}_{L}$

Substituting ic, this equation becomes:

$\dot{z} - \dot{z}_L = L C \dot{z}_L + R C \dot{z}_L$

rearranging to have is terms on LHS:
